

# Cormen Ch. 3 - Growth of Functions

---

- running time growth = asymptotic efficiency
- interested in input size vs. output size as it approaches a limit when the input is increased without bound

## Asymptotic notation

---

- input domain is natural numbers  $N = \{0, 1, 2, 3, \dots\}$
- sometimes extended to real numbers  $R$

## Asymptotic notation, functions, and running times

- generally reduce to largest element for running time
- can be used to characterize memory usage and other algorithmic details

## $O(\theta)$ -notation

- for a given function,  $g(n)$ , denote  $O(g(n))$  as the set of functions:  $O(g(n)) = \{f(n) : \text{for positive constants } c_1, c_2, \text{ and } n_0 \text{ such that } 0 \leq c_1 g(n) \leq f(n) \leq c_2 g(n) \text{ for all } n \geq n_0\}$
- this means that the  $O(\theta)$ -descriptive function should always bound  $f(n)$  between  $c_1 g(n)$  and  $c_2 g(n)$
- $f(n)$  is equal to  $g(n)$  to within a constant factor, i.e.  $g(n)$  is an asymptotically tight bound
- $f(n)$  must be asymptotically non-negative, i.e. positive for sufficiently large  $n$
- asymptotically positive - positive for all sufficiently large  $n$

## $O(\mu)$ -notation

- $O(\theta)$  bounds from above and below
- $O(\mu)$  is used when there is only an asymptotic upper bound
- for a given function,  $g(n)$ , denote  $O(g(n))$  as the set of functions:  $O(g(n)) = \{f(n) : \text{for positive constants } c \text{ and } n_0 \text{ such that } 0 \leq f(n) \leq c g(n) \text{ for all } n \geq n_0\}$
- weaker than  $O(\theta)$  notation
- inclusion in a set defined by  $O(\theta)$  notation implies inclusion in a related set for  $O(\mu)$

## $O(\omega)$ -notation

- provides only an asymptotic lower bound
- for a given function,  $g(n)$ , denote  $O(g(n))$  as the set of functions:  $O(g(n)) = \{f(n) : \text{for positive constants } c \text{ and } n_0 \text{ such that } 0 \leq c g(n) \leq f(n) \text{ for all } n \geq n_0\}$

- Theorem 3.1 ->
  - For any two functions  $f(n)$  and  $g(n)$ , we have  $f(n) = O(\theta)(g(n))$  if and only if  $f(n) = O(\omicron)(g(n))$  and  $f(n) = \Omega O(\omega)(g(n))$
- omega notation means the minimum cost (running time/memory) will be at least some constant times the given bound  $g(n)$  for all sufficiently large  $n$

## Asymptotic notation in equations and inequalities

- asymptotic notation is beneficial for communicating about and comparing equations/ algorithms because it removes inessential terms for that sake of focusing on the main factoring term

## o-notation (little-o)

- used to denote an upper bound that is not asymptotically tight
- for a given function,  $g(n)$ , denote  $o(g(n))$  as the set of functions:  $o(g(n)) = \{f(n): \text{for positive constants } c > 0 \text{ and } n_0 > 0 \text{ such that } 0 \leq f(n) \leq c \cdot g(n) \text{ for all } n \geq n_0\}$
- similar to  $O(\omicron)$ -notation
  - omicron specifies that the conditions hold for SOME constant  $c > 0$
  - little-o holds for ALL constants  $c > 0$
- implies limit of  $f(n) / g(n)$  as  $n \rightarrow \infty$  is 0

## w-notation (lower-case theta)

- same as little-o but specifies a lower bound that is not asymptotically tight

## Comparing functions

- transitivity holds for all notations
  - $f(n) = O(g(n))$  and  $g(n) = O(h(n))$  implies  $f(n) = O(h(n))$
- reflexivity holds for all big-O notations
  - $f(n) = O(f(n))$
- symmetry holds only for  $O(\theta)$ -notation
  - $f(n) = O(g(n))$  if and only if  $g(n) = O(f(n))$
- transpose symmetry holds for  $O(\omega)$  and w-notation
